Summary

- Gaussian processes are powerful and elegant models, but exact inference requires $\mathcal{O}(n^3)$ computations, where n is the number of training data
- We propose the Tensor Train GP (TT-GP) framework with linear complexity $\mathcal{O}(n)$
- TT-GP allows to build flexible posterior approximations and train expressive deep kernels by using billions of inducing points for datasets containing millions of data points of dimensionality up to 10
- TT-GP achieves state-of-the-art results on several important benchmarks both with RBF and deep kernels

Inducing Inputs and Structured Kernel Interpolation

- Inducing points (Z, u) are m imaginary points that compress information in data. The joint distribution of labels y , process values $f \in \mathbb{R}^n$ at data points and $u \in \mathbb{R}^m$ at inducing points is given by

$$p(y, f, u) = \prod_i p(y_i|f) \cdot p(f|u) \cdot p(u),$$

where $p(f|u) = \mathcal{N}(f|K_{nm}K_{mm}^{-1}u, K_{nn} - K_{nm}K_{mm}^{-1}K_{nm}^T)$, $p(u) = \mathcal{N}(u|0, K_{mm})$. Here $K_{mm} \in \mathbb{R}^{m \times m}$, $K_{nm} \in \mathbb{R}^{n \times m}$, $K_{nn} \in \mathbb{R}^{n \times n}$ are covariance matrices computed between Z and Z , X and Z , X and X respectively

- SKI (Wilson and Nickisch, 2015): set inducing points on a multi-dimensional grid

$$Z = Z^1 \times Z^2 \times \dots \times Z^D$$

Assume the kernel decomposes as $k(x, x') = k^1(x^1, x'^1) \cdot k^2(x^2, x'^2) \cdot \dots \cdot k^D(x^D, x'^D)$. Covariance matrix K_{mm} takes form $K_{mm} = K_{m_1 m_1}^1 \otimes K_{m_2 m_2}^2 \otimes \dots \otimes K_{m_D m_D}^D$

- $\det(K_{mm})$ and K_{mm}^{-1} can be computed efficiently
- Inducing points can be considered as interpolation points for the kernel

$$k_i \approx K_{mm} w_i,$$

where $k_i \in \mathbb{R}^m$ is the vector of covariances between the i -th training object and the inducing points, $w_i \in \mathbb{R}^m$ is the vector of interpolation coefficients

- KISS-GP uses cubic convolutional interpolation for which

$$w_i = w_i^1 \otimes w_i^2 \otimes \dots \otimes w_i^D$$

Gaussian Process ELBO

Evidence Lower Bound (Hensman et al., 2013) with KISS-GP approximation of k_i :

$$\log p(y) \geq \sum_{i=1}^n \left(\log \mathcal{N}(y_i | w_i^T \mu, \sigma^2) - \frac{1}{2\sigma^2} (\delta - w_i^T K_{mm} w_i) - \frac{1}{2\sigma^2} \text{tr}(w_i^T \Sigma w_i) \right) - \frac{1}{2} \left(\log \frac{\det(K_{mm})}{\det(\Sigma)} - m + \text{tr}(K_{mm}^{-1} \Sigma) + \mu^T K_{mm}^{-1} \mu \right)$$

where σ^2 is the noise variance, δ is the prior variance of the process at any point and $\mu \in \mathbb{R}^m$, $\Sigma \in \mathbb{R}^{m \times m}$ are variational parameters

Tensor Train Format

Tensor \mathcal{A} is said to be represented in Tensor Train (Oseledets, 2011) format if:

$$\mathcal{A}_{i_1 \dots i_d} = \underbrace{G_1[i_1]}_{1 \times r} \underbrace{G_2[i_2]}_{r \times r} \dots \underbrace{G_d[i_d]}_{r \times 1}$$

An example of computing one element of a 4-dimensional tensor:

- TT-format uses $\mathcal{O}(dnr^2)$ memory to approximate a tensor with n^d elements
- Allows for efficient implementation of linear algebra operations

TT-GP

- Set inducing points Z on a grid in the feature space
- Restrict Σ to be in a Kronecker product format $\Sigma = \Sigma^1 \otimes \Sigma^2 \otimes \dots \otimes \Sigma^D$
- Represent μ as a d -dimensional tensor, restrict to be in TT format with TT-ranks r
- Maximize ELBO with respect to TT-cores of μ , Kronecker factors of Σ using stochastic optimization

Properties

- Linear computational complexity in the size of the data $\mathcal{O}(nDm^{1/D}r^2 + Dm^{1/D}r^3 + Dm^{3/D})$. TT-ranks are in general on the scale of $r \approx 10$. Here $m = m_0^D$, where m_0 is the number of inducing points per dimension
- TT-GP can be applied for $n \approx 10^6$ and $m \approx 10^{10}$

RBF Kernel Experiments

Dataset		SVI-GP / KLSP-GP				TT-GP
