# Scalable Gaussian Processes with Billions of Inducing Inputs

## via Tensor Train Decomposition **Pavel Izmailov**

#### Alexander Novikov

pi49@cornell.edu

Summary

sasha.v.novikov@gmail.com

#### • Gaussian processes are powerful and elegant models, but exact inference requires $\mathcal{O}(n^3)$ computations, where n is the number of training data

- We propose the Tensor Train GP (TT-GP) framework with linear complexity  $\mathcal{O}(n)$
- TT-GP allows to build flexible posterior approximations and train expressive deep kernels by using billions of inducing points for datasets containing millions of data points of dimensionality up to 10
- TT-GP achieves state-of-the-art results on several important benchmarks both with RBF and deep kernels

#### **Inducing Inputs and Structured Kernel Interpolation**

- Inducing inputs are imaginary data points that allow to speed up GP inference
- SKI (Wilson and Nickisch, 2015): set inducing points on a multi-dimensional grid

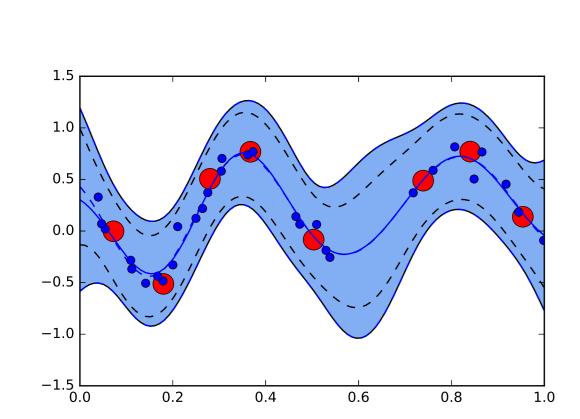

$$Z = Z^1 \times Z^2 \times \ldots \times Z^D.$$

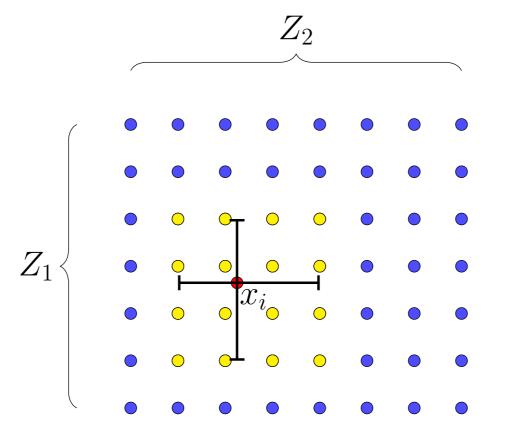

Assume the kernel decomposes as

$$k(x, x') = k^{1}(x^{1}, x'^{1}) \cdot k^{2}(x^{2}, x'^{2}) \cdot \dots \cdot k^{D}(x^{D}, x'^{D})$$

Covariance matrix  $K_{mm} \in \mathbb{R}^{m \times m}$  computed at the inducing points takes form

$$K_{mm} = K_{m_1m_1}^1 \otimes K_{m_2m_2}^2 \otimes \ldots \otimes K_{m_Dm_D}^D$$

- $\det(K_{mm})$  and  $K_{mm}^{-1}$  can be computed efficiently
- Inducing points can be considered as inteprolation points for the kernel

$$k_i \approx K_{mm} w_i$$

where  $k_i \in \mathbb{R}^m$  is the vector of covariances between the *i*-th training object and the inducing points,  $w_i \in \mathbb{R}^m$  is the vector of interpolation coefficients

• KISS-GP uses cubic convolutional interpolation for which

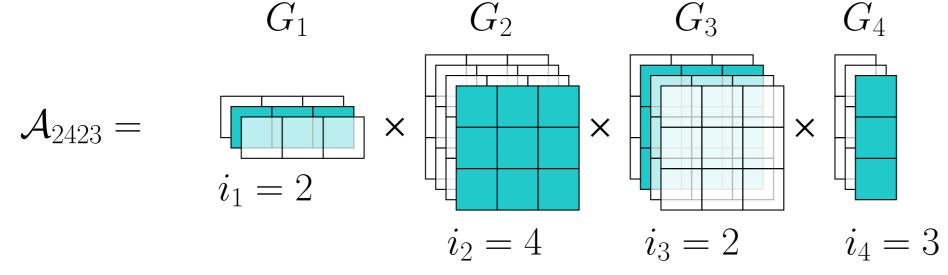

$$w_i = w_i^1 \otimes w_i^2 \otimes \ldots \otimes w_i^D$$

### **Tensor Train Format**

Tensor  $\mathcal{A}$  is said to be represented in Tensor Train (Oseledets, 2011) format if:

$$\mathcal{A}_{i_1...i_d} = \underbrace{G_1[i_1]}_{1 \times r} \underbrace{G_2[i_2]}_{r \times r} \dots \underbrace{G_d[i_d]}_{r \times 1}$$

An example of computing one element of a 4-dimensional tensor:

- TT-format uses  $O(dnr^2)$  memory to approximate a tensor with  $n^d$  elements
- Allows for efficient implementation of linear algebra operations

#### **Gaussian Process ELBO**

Evidence Lower Bound (Hensman et al., 2013) with KISS-GP approximation of  $k_i$ :

$$\log p(y) \ge \sum_{i=1}^{n} \left( \log \mathcal{N}(y_i | w_i^T \mu, \sigma^2) - \frac{1}{2\sigma^2} (\delta - k_i^T K_{mm}^{-1} k_i) - \frac{1}{2\sigma^2} \operatorname{tr}(w_i^T \Sigma w_i) \right)$$
$$-\frac{1}{2} \left( \log \frac{\det(K_{mm})}{\det(\Sigma)} - m + \operatorname{tr}(K_{mm}^{-1} \Sigma) + \mu^T K_{mm}^{-1} \mu \right)$$

#### where

- $\sigma^2$  is the noise variance
- $\delta$  is the prior variance of the process at any point
- $\mu \in \mathbb{R}^m$ ,  $\Sigma \in \mathbb{R}^{m \times m}$  variational parameters

#### **TT-GP**

- Set inducing points Z on a grid in the feature space
- Restrict  $\Sigma$  to be in a Kronecker product format

**Dmitry Kropotov** 

dmitry.kropotov@gmail.com

$$\Sigma = \Sigma^1 \otimes \Sigma^2 \otimes \ldots \otimes \Sigma^D$$

- Represent  $\mu$  as a d-dimensional tensor, restrict to be in TT format with TT-ranks r
- Maximize ELBO with respect to TT-cores of  $\mu$ , Kronecker factors of  $\Sigma$  using SGD

#### **Properties**

• Linear computational complexity in the size of the data  $\mathcal{O}(nDm^{1/D}r^2 + Dm^{1/D}r^3 + Dm^{3/D})$ . TT-ranks are in general on the scale of  $r \approx 10$ .

Here  $m = m_0^D$ 

• TT-GP can be applied for very large n and m

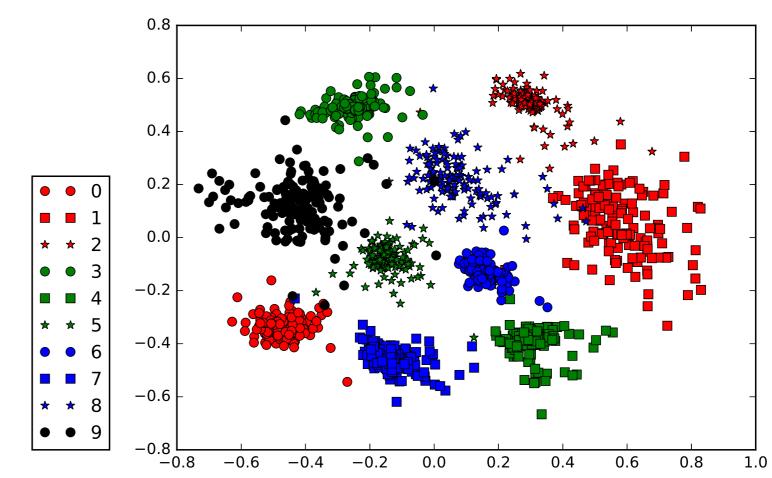

#### **RBF Kernel Experiments**

Comparison with SVI-GP (Hensman et al., 2013) on regression and classification tasks:

Dataset			SVI-GP / KLSP-GP			TT-GP			
Name	$\overline{n}$	$\overline{D}$	acc.	$\overline{m}$	t (s)	acc.	$\overline{m}$	$\overline{d}$	<i>t</i> (s)
Powerplant	7654	4	0.94	200	10	0.95	$35^4$	-	5
Protein	36584	9	0.50	200	45	0.56	$30^{9}$	-	40
YearPred	463K	90	0.30	1000	597	0.32	$10^{6}$	6	105
Airline	6M	8	0.665*	-	_	0.694	$20^{8}$	-	5200
svmguide1	3089	4	0.967	200	4	0.969	$20^{4}$	_	1
EEG	11984	14	0.915	1000	18	0.908	$12^{10}$	10	10
covtype bin	465K	54	0.817	1000	320	0.852	$10^{6}$	6	172

#### **Deep Kernel Experiments**

Embedding learned by TT-GP with a deep kernel on *digits* dataset:

Comparison with SV-DKL (Wilson et al., 2016) and stand-alone DNN:

Dataset		SV-DKL	DNN		TT-GP		
Name	n	acc.	acc.	<i>t</i> (s)	acc.	d	t (s)
Airline	6M	0.781	0.780	1055	$\boldsymbol{0.788 \pm 0.002}$	2	1375
CIFAR-10	50K	_	0.915	166	$0.908 \pm 0.003$	9	220
<b>MNIST</b>	60K	_	0.993	23	$0.9936 \pm 0.0004$	10	64
